Understanding Atomic Force Microscopy

What Is Atomic Force Microscopy?

Atomic Force Microscopy is a type of scanning probe microscopy that provides topographical and surface property information at nanometer and even sub-nanometer resolutions. Unlike optical microscopy, AFM employs a sharp probe, often made of silicon or silicon nitride, that "feels" the surface of a sample, allowing detailed imaging of complex nanostructures.

The core principle involves a cantilever with a finely pointed tip that interacts with the sample surface. As the tip scans across the surface, forces between the tip and the sample cause the cantilever to deflect. These deflections are detected using laser beams reflected onto photodetectors, translating mechanical movements into high-resolution images.

How AFM Works in Process Engineering

In process engineering, AFM operates in various modes tailored to specific analysis needs:

- Contact Mode: The tip maintains constant contact with the surface, ideal for measuring surface roughness and mechanical properties.
- Tapping Mode: The cantilever oscillates near its resonance frequency, intermittently contacting the surface, reducing damage and providing phase imaging.
- Non-Contact Mode: The tip hovers just above the surface, sensing weak forces, suitable for delicate samples.

These modes enable detailed surface characterization, measurement of nanomechanical properties,

and real-time process monitoring.
