Introduction to Chebyshev Wavelets

Chebyshev wavelets are a class of wavelet functions derived from Chebyshev polynomials, which are a set of orthogonal polynomials with remarkable approximation properties. Unlike classical wavelets like Haar or Daubechies, Chebyshev wavelets leverage the spectral properties of Chebyshev polynomials, making them highly effective in representing functions with rapid oscillations or boundary layers.

The specific focus here is on the second kind Chebyshev wavelets, which are based on Chebyshev polynomials of the second kind, denoted as $U_n(x)$. These polynomials are orthogonal over the interval $[-1, 1]$ with respect to the weight function $\sqrt{1-x^2}$, and their associated wavelets inherit many beneficial features from this orthogonality.

Understanding Second Kind Chebyshev Polynomials

Definition and Properties

The Chebyshev polynomials of the second kind, $U_n(x)$, are defined as:

$$U_n(\cos \theta) = \frac{\sin((n+1)\theta)}{\sin \theta}$$

for

$n = 0, 1, 2, \dots$.

Key features include:

- Orthogonality over $[-1, 1]$ with weight $(\sqrt{1 - x^2})$.
- Recursion relation:

$$[$$

$$U_{n+1}(x) = 2x U_n(x) - U_{n-1}(x)$$

$$]$$

- Explicit expression:

$$[$$

$$U_n(x) = \frac{\sin((n+1)\theta)}{\sin \theta}$$

$$]$$

where $(x = \cos \theta)$.

Relevance to Wavelet Construction

These properties make $(U_n(x))$ suitable for generating wavelet bases because of their orthogonality, recurrence relations, and spectral efficiency. By scaling and translating these polynomials, one constructs wavelet functions that form bases for function spaces over $[-1, 1]$, which can then be adapted to various problem domains.

Construction of Second Kind Chebyshev Wavelets

Wavelet Basis Design

The second kind Chebyshev wavelets are constructed by:

- Dividing the domain $[-1, 1]$ into sub-intervals.
- Using scaled and shifted versions of $(U_n(x))$ to form basis functions localized to each sub-interval.
- Ensuring orthogonality and completeness over the domain.

Mathematically, the wavelets are often defined as:

$$\psi_{j,k}(x) = \sqrt{w_j} U_{n_j} \left(\frac{2^j x - k}{2^j} \right)$$

$$\psi_{j,k}(x) = \sqrt{w_j} U_{n_j} \left(\frac{2^j x - k}{2^j} \right)$$

$$\psi_{j,k}(x) = \sqrt{w_j} U_{n_j} \left(\frac{2^j x - k}{2^j} \right)$$

where:

- j represents the scale level,
- k indexes the position,
- w_j is a normalization factor,
- n_j determines the polynomial degree at scale j .

This construction ensures multiresolution analysis capability, allowing functions to be approximated at various levels of detail.

Application to Differential Equations

Wavelet-Based Collocation and Galerkin Methods

Chebyshev wavelets are widely used in spectral and wavelet collocation methods for solving differential equations. The key idea involves expanding the unknown function $u(x)$ in terms of the wavelet basis:

$$u(x) \approx \sum_{j,k} c_{j,k} \psi_{j,k}(x)$$

$$u(x) \approx \sum_{j,k} c_{j,k} \psi_{j,k}(x)$$

$$u(x) \approx \sum_{j,k} c_{j,k} \psi_{j,k}(x)$$

where $\{c_{j,k}\}$ are the coefficients to be determined.

By substituting the wavelet expansion into the differential equation and applying collocation or Galerkin procedures, one reduces the continuous problem to a system of algebraic equations.
